INFORMATION SECURITY SURVEILLANCE USE CASES GUIDELINE

Information Security Surveillance use cases Guideline	
Framework type	Information security guideline
Guidelines owner	Louis Buteau-Vaillancourt, Director, Information Security Protection and Analysis
Guidelines objectives	Provide developers, integrators, designers, and architects with aggregated guidance on defining information security events surveillance cases. These guidelines support the application of the Security Monitoring and Analysis Standard.
Effective date	2025-03-10
Frequency of review	Once (1) per two years or following major changes

Confidentiality notice

1. Introduction

1.1. Scope

The Information Security Surveillance use cases Guideline applies to iA Financial Group (iAFG) employees, service providers, subcontractors, consultants, and any person whose work is under the responsibility of the Company's management, over whom the Company exercises direct control and who uses the assets of iA Financial Group.

This guide supports the application of the Monitoring and Analysis Security Standard and details the requirements related to the surveillance of information security events. Its goal is to present the principles, guidelines, best practices or details of how to define surveillance cases. It is specifically intended for IT teams that needs guidance on how to document information security surveillance use cases and events that would typically be configured in a Security Information and Event Management (SIEM) platform.

The use of "iA Financial Group" or the "Company" in this document refers to iA Financial Corporation Inc. and its subsidiaries.

2. Elements needed to define a surveillance use case

The following elements must be provided to the information security surveillance team in order for them to develop the use case:

2.1. What risk does the surveillance use case mitigate and it's surveillance objective ?

A use case should always be developed following a risk analysis done by the IS Consulting team that determines that a specific event may pose a cybersecurity risk if not monitored. Examples of risks could be from external threats (e.g., malware, phishing) and internal threats (e.g., insider threats, unauthorized access).

Establish clear surveillance objectives for each asset, aligned with the organization's security goals and regulatory requirements. These objectives should be aligned with NIST CSF categories such as, Detect and Respond.

Example:

- Protect the organisation by blocking illegal downloading of sensitive information.

2.2. Example of the security event and example of the log that would be produced (if possible).

This helps our incident response team have an idea of what the security event entails and allows them to define how to respond in case of an alert.

Example:

- Alert when a known malicious IP address communicates with internal systems.

2.3. What logs will be required in order to assure the detection and investigation of the security event ?

List all data sources required for monitoring this event, such as logs from firewalls, intrusion detection systems, and user activity logs as well as additional logs required to investigate properly the event by the incident response team. Also, specify is a correlation of different events are required to detect the use case and how we can test the use case.

2.4. What does the incident response team need to check to see if we are facing a real security incident ?

If there are legitimate reasons for this event to happen, the incident response team needs to be made aware of them in order to close the event as false positive if a legitimate situation occurs. We also need to know who are the business and IT contacts that could help with the investigation of the use case.
